

Class 36: Proposal Presentations, Part 2

Session 36 of 36 – Second Half, and Closing the Course

Data-driven Systems Engineering

18 December

Agenda

- Logistics for the second half
- Quick recap of the rubric
- Closing the course: from Class 1 to Class 36
- Thanks, and what comes next

Same rubric, remaining teams, then we close

Learning goals

- Continue today's presentations under the same format and rubric as this morning.
- Give and receive feedback consistently across both halves of the day.
- Connect today's work back to the full 36-session arc of the course.

Course Map and Running Cases

Today in the course

Focus: Continuing today's presentations and closing the 36-session course.

Bridge: The rubric and format from Class 35 carry over unchanged; this is the same session split across the day for scheduling, not a new topic.

Fraud case

Fraud-pattern projects and their variations have anchored one half of this course's running examples since Class 1.

Pasteurization case

Pasteurization-pattern projects and their variations have anchored the other half in the same way.

Course thread: The Problem, Data, Features, Model, Interface, Delivery, Monitor, Evolution map used since the first class map is the same map every team's project should now fit into.

Logistics for the second half

- Same format as this morning: 10 minutes presenting, 5 minutes of questions per team.
- Remaining teams present in the posted order; be ready 5 minutes before your slot.
- The same rubric from Class 35 applies without change.
- Written peer feedback is still expected from every non-presenting team.

Rubric, quick recap

Criterion	What reviewers look for
Problem clarity	A specific problem and user, not a vague topic area.
Feasibility	Scope matches the time and data actually available.
Lifecycle coverage	Requirements, delivery, and monitoring are at least sketched.
Risk awareness	Real risks are named, with a plausible response.
Communication	The team can explain choices and answer questions clearly.

Closing the course: the full arc

- Thirty-six sessions, two running cases, and one repeated question: is this a good model, or a good system?

What should stay with you

- Python and modeling skills are necessary but not sufficient on their own.
- Requirements, process, and delivery discipline are what let a model become a system others can trust.
- Monitoring and scaling are not afterthoughts; they are where systems actually get tested, in production, over time.
- The fraud and pasteurization cases were vehicles for these ideas, not the point of the course.

Question

What is the one habit from this course you intend to keep using after today, on a project this course never assigned?

- This closes the course on transfer, not recall.
- There is no wrong answer; the point is naming something specific enough to actually keep doing.

Thanks

- Thank you for thirty-six sessions of work, questions, and projects.
- The two running cases, fraud detection and pasteurization monitoring, were teaching tools; your own projects are the real outcome.
- Keep the habits: write the requirement down, test before you trust it, watch it after you ship it.

Papers and materials

From This Class to the Next

What stays with us

- A finished proposal defense is evidence of the full lifecycle habit this course tried to build.
- Software engineering, data-driven methods, and MLOps are one integrated way of building systems, not three separate topics.
- The systems view from the very first class map is the same view every team just defended.

Project use

Your presented plan, and the feedback you received today, are what carry directly into building and delivering the actual project.

Next connection

There is no Class 37; what comes next is project execution, delivery, and the final evaluation of each team's system.

Course thread: The course closes with the same question it opened with: not just whether the model works, but whether the system around it can be trusted.
